## HYGROMYCIN A DERIVATIVES AS ANTIBACTERIAL AGENTS

Background Of The Invention

This invention relates to novel hygromycin A derivatives that are useful as antibacterial and antiprotozoal agents in mammals, including man, as well as in fish and birds. This invention also relates to pharmaceutical compositions containing the novel compounds and to methods of treating bacterial and protozoal infections in mammals, fish and birds by administering the novel compounds to mammals, fish and birds requiring such treatment.

Hygromycin A is a fermentation-derived natural product first isolated from *Streptomyces hygroscopicus* in 1953. As an antibiotic, hygromycin A possesses activity against human pathogens and is reported to possess potent *in vitro* activity against *Serpulina* (*Treponema*) *hyodysenteriae* which causes swine dysentery. Several references refer to semisynthetic modifications of hygromycin A, including the following: derivatization of the 5" ketone of hygromycin A to the 2,4-dinitrophenylhydrazone is referred to in K. Isono et al., *J. Antibiotics* **1957**, 10, 21, and R.L. Mann and D.O. Woolf, *J. Amer Chem. Soc.* **1957**, 79, 120. K. Isono et al., *ibid.*, also refer to the thiosemicarbazone at 5"; reduction of the 5" ketone of hygromycin A to the 5" alcohol is referred to in R.L. Mann and D.O. Woolf, *ibid.*, as well as in S.J. Hecker et al., *Bioorg. Med. Chem. Lett.* **1992**, 2, 533 and S.J. Hecker et al., *Bioorg. Med. Chem. Lett.* **1993**, 3, 295; furanose analogues are referred to in B.H. Jaynes et al., *Bioorg. Med. Chem. Lett.* **1993**, 3, 1531, and B.H. Jaynes et al., *J. Antibiot.* **1992**, 45, 1705; aromatic ring analogues are referred to in S.J. Hecker et al., *Bioorg. Med. Chem. Lett.* **1993**, 3, 289, and C.B. Cooper et al., *Bioorg. Med. Chem. Lett.* **1997**, 7, 1747; enamide analogues are referred to in S.J. Hecker et al., *Bioorg. Med. Chem. Lett.* **1992**, 2, 533; aminocyclitol analogues are referred to in S.J. Hecker et al., *Bioorg. Med. Chem. Lett.* **1992**, 2, 1015, and in S.J. Hecker et al., *Bioorg. Med. Chem. Lett.* **1992**, 2, 1043. The hygromycin A derivatives of the present invention possess broad activity against both gram-negative and gram-positive bacteria and protozoa. Hygromycin A derivatives are also described and claimed in United States provisional patent application numbers 60/084042 (filed May 4, 1998) and 60/084058 (filed May 4, 1998), both of which United States provisional applications are incorporated herein by reference in their entirety.

Detailed Description of the Invention

The preparation of the compounds of the present invention is illustrated in the following Scheme.

Scheme

5       The compounds of the present invention are readily prepared. With reference to the Scheme illustrated above, the starting compound of formula 2 is hygromycin A which may be prepared according to procedures known to those skilled in the art, such as by fermentation of *Streptomyces hygroscopicus* NRRL 2388. The methyl ketone at 4" on the furanose sugar of the hygromycin A molecule can exist in the S configuration (hygromycin A) or R configuration (epi-hygromycin) on the furanose sugar. When published protocols are used as a model for fermentation and recovery of hygromycin A (U.S. Patent 3,100,176; Antibiotic Chemotherapy (1953)3:1268-1278, 1279-1282), the hygromycin product is an approximately 3:1 mixture of hygromycin A (the 4"-(S) epimer), with the beta-oriented methyl ketone on the furanose sugar, as drawn, and epi-hygromycin. It is known in the literature (Journal of Antibiotics 33(7), 695-704, 1980) that pure hygromycin A will convert to epi-hygromycin in alkaline solutions. By carefully controlling the pH below 6.9 during the fermentation, and the pH, temperature and solvent exposure during the purification process, the final recovered product may be improved to at least a 14:1 ratio of hygromycin A : epi-hygromycin. Using this material, substantially single isomers derived from the 4"-(S) hygromycin may be prepared for use as templates for further synthetic modification.

Hygromycin A enriched for the 4"-(S) epimer is produced by fermentation of *Streptomyces hygroscopicus* NRRL2388, or mutants thereof, in media with pH controlled at less than 6.9, preferably 6.2 to 6.7, throughout the process. The medium contains assimilable sources of carbon, nitrogen and trace elements, as known to those skilled in the art. The fermentation is run at a temperature of about 25-35°C, preferably about 29°C. The fermentation is monitored, for example by high pressure liquid chromatography. Incubation is continued until the yield of the compound reaches a maximum, generally for a period of about 3 to 10 days, preferably about 4 to 6 days.

The formation of epi-hygromycin is minimized during the purification process by using an aqueous buffer (rather than unbuffered water) and controlling the pH of the active streams to near 6.0. Epi-hygromycin formation is also minimized by minimizing the time the recovered material is subject to higher temperatures. Thus, where it is necessary to reduce solvent concentrations, it is preferred to dilute active streams with the aqueous buffer and avoid use of rotary evaporation at elevated temperatures. Also, as means of avoiding higher temperatures, a resin column may be used to concentrate the active solution prior to the final purification step in order to reduce the volume of solution that must be boiled. The final purification step in the process is the concentration of the active cuts to solids using vacuum and a bath temperature of about 35-50°C. The period in which the solution is subject to elevated temperatures may be minimized by boiling in stages.

40       The compound of formula 1 where R<sup>2</sup> is defined as above, X<sup>1</sup> is CH<sub>2</sub>, X<sup>2</sup> is O and R<sup>3</sup> is H may be prepared through the corresponding α,β-unsaturated ester intermediates derived

5 from Wittig, Horner-Emmons or Peterson olefination of the C-5' ketone of hygromycin A. For instance, (carbethoxymethylene)triphenylphosphorane or (carbethoxyethylidene)triphenylphosphorane can be reacted with hygromycin A to provide the unsaturated ethyl ester. At this point the hydroxy groups of hygromycin A may be appropriately protected, for instance as their silyl ethers using an appropriate reagent such as triethylsilyl chloride (TESCl), trimethylsilyl chloride (TMSCl) or *tert*-butyldimethylsilyl chloride (TBDMSCl) and an amine base, such as imidazole or pyridine. This compound may then be reduced, for instance with diisobutyl aluminum hydride, and deprotection of the hydroxyl groups may be carried out by use of acid, such as acetic acid or fluoride ion, such as TBAF.

15 The compounds of formula 1 where R<sup>1</sup> is H and where R<sup>2</sup> is defined as above, X<sup>1</sup> is CH<sub>2</sub>, X<sup>2</sup> is O and R<sup>3</sup> is H can be prepared through the corresponding  $\alpha,\beta$ -unsaturated ester intermediates derived from Wittig, Horner-Emmons or Peterson olefination of the C-5' ketone of 2"-deoxy-pentaprotected hygromycin A. In this process hygromycin A is prepared by protection of all of the hydroxy groups of hygromycin A, with the exception of the hydroxy at the 2" carbon (C-2"), as their silyl ethers using an appropriate reagent such as triethylsilyl chloride (TESCl), trimethylsilyl chloride (TMSCl) or *tert*-butyldimethylsilyl chloride (TBDMSCl). The preferred method is 10 eq of TBDMSCl and imidazole in N,N-dimethylformamide (DMF) at a temperature of 25-40°C for 12-36 hours. The 2"-deoxy-pentaprotected hygromycin A is then prepared by removal of the hydroxy group using the method of Barton et al., *J. Chem Soc., Perkin Trans. I* 1975, 1574. The preferred method in this case is the method of Genu-  
20 Dellac et al., *Carbohydrate Res.* 1991, 216, 249. The aforementioned  $\alpha,\beta$ -unsaturated ester may then be prepared via a Wittig, Horner-Emmons or Peterson olefination of the C-5' ketone of 2"-deoxy-pentaprotected hygromycin A. For instance, (carbethoxymethylene)triphenylphosphorane or (carbethoxyethylidene)triphenyl-phosphorane can be reacted with hygromycin A to provide the unsaturated ethyl ester. This compound may  
30 then be reduced, for instance with diisobutyl aluminum hydride, and deprotection of the hydroxyl groups may be carried out by use of acid, such as acetic acid or fluoride ion, such as TBAF.

The compound of formula 1 where R<sup>1</sup> and R<sup>2</sup> are defined as above, X<sup>1</sup> is CH<sub>2</sub>, X<sup>2</sup> is O and R<sup>3</sup> is -C(O)(CR<sup>6</sup>R<sup>7</sup>)<sub>t</sub>(C<sub>6</sub>-C<sub>10</sub> aryl), wherein R<sup>6</sup>, R<sup>7</sup> and "t" are as defined above, may be  
35 prepared via acylation of protected hygromycin allyl alcohol described above; for example by treatment of said alcohol with X-C(O)(CR<sup>6</sup>R<sup>7</sup>)<sub>t</sub>(C<sub>6</sub>-C<sub>10</sub> aryl), wherein X is a leaving group such as Cl, Br or N-hydroxysuccinimide (NHS) ester, in the presence of a base, such as sodium hydride, triethylamine or potassium *tert*-butoxide. The protecting groups may then be removed as above.

40 The compound of formula 1 where R<sup>1</sup> and R<sup>2</sup> are defined as above, X<sup>1</sup> is CH<sub>2</sub>, X<sup>2</sup> is O and R<sup>3</sup> is -(CR<sup>6</sup>R<sup>7</sup>)<sub>t</sub>(C<sub>6</sub>-C<sub>10</sub> aryl), wherein R<sup>6</sup>, R<sup>7</sup> and "t" are as defined above, may be prepared

5 via alkylation of protected hygromycin allyl alcohol described above; for example by treatment of said alcohol with  $X-(CR^6R^7)_l(C_6-C_{10} \text{ aryl})$ , wherein X is a leaving group such as Cl, Br or mesylate, in the presence of a base, such as sodium hydride, triethylamine or potassium *tert*-butoxide. The protecting groups may then be removed as above.

10 The compound of formula 1 where  $R^1$  and  $R^2$  are defined as above,  $X^1$  is  $CH_2$ ,  $X^2$  is O or S, "t" is 0 and  $R^3$  is  $-(CR^6R^7)_l(C_6-C_{10} \text{ aryl})$ , wherein  $R^6$  and  $R^7$  are as defined above, may also be prepared via a Mitsunobu reaction. The protected hygromycin allyl alcohol, prepared as described above, is subjected to a Mitsunobu reaction with  $HO-(CR^6R^7)_l(C_6-C_{10} \text{ aryl})$  or  $HS-(CR^6R^7)_l(C_6-C_{10} \text{ aryl})$ , mediated by triphenylphosphine and diethyl azodicarboxylate as described in D.L. Hughes, Org. Reactions (1992) 42 335. The resulting ether or thioether may  
15 then be deprotected as described above or in the case of the thioether may be oxidized, for instance with *m*-CPBA, and then deprotected as described above.

The compound of formula 1 where  $R^1$  and  $R^2$  are defined as above,  $X^1$  is  $CH_2$ ,  $X^2$  is O and  $R^3$  is  $-C(O)NR^6(CR^6R^7)_l(C_6-C_{10} \text{ aryl})$ , wherein  $R^6$ ,  $R^7$  and "t" are defined above, may be prepared by reacting protected hygromycin allyl alcohol, prepared as described above, with  
20 isocyanate  $OCNR^6(CR^6R^7)_l(C_6-C_{10} \text{ aryl})$ , in toluene at temperatures from 40°C to 110°C, preferably 50 - 80°C. Addition of dimethylaminopyridine and triethylamine to the reaction may be advantageous. The protecting groups may then be removed as above.

The compound of formula 1 where  $R^1$  and  $R^2$  are defined as above,  $X^1$  is  $CH_2$ ,  $X^2$  is N and  $R^3$  is defined as above, with the proviso that nitrogen is not adjacent to a carbonyl  
25 functionality, may be prepared via reduction amination of protected hygromycin aldehyde, prepared by the oxidation of the allyl alcohol above: (1) the allyl alcohol may be oxidized, for example using Swern conditions as described in T Tidwell, Org. Reactions (1990) 39 297, (2) and combined with  $HN(R^6)-R^3$  in an inert solvent and then (3) treated with a reducing agent such as  $NaBH_4$ ,  $NaBH(OAc)_3$  (Ac is acetyl), or  $NaCNBH_3$ .  $R^6$  may be introduced as part of  
30  $HN(R^6)-R^3$  in step (2) or introduced after step (3), wherein  $H_2NR^3$  was used, via alkylation, for instance with a base such as sodium hydride or potassium *tert*-butoxide and an alkylating agent such as  $R^6-X$  where X is Br, Cl or methanesulfonate.

The compound of formula 1 where  $R^1$  and  $R^2$  are defined as above,  $X^1$  is  $NR^6$ , S or  $S(O)_n$ ,  $X^2$  is C or  $NR^6$  and  $R^3$  is  $-(CR^6R^7)_l(C_6-C_{10} \text{ aryl})$ , wherein  $R^6$ ,  $R^7$  and "t" are defined  
35 above, may be prepared by the Peterson Olefination reaction as described in D. Ager, Org. Reactions (1990) 38 1. For example, protected hygromycin ketone, prepared by reacting the appropriate reagent such as triethylsilyl chloride (TESCl), trimethylsilyl chloride (TMSCl) or *tert*-butyldimethylsilyl chloride (TBDMS) and imidazole or pyridine with hygromycin A, may be reacted with  $TMS-CH(R^2)-X^1-X^2-R^3$  in the presence of a strong base, for example lithium  
40 diisopropylamide or butyl lithium. When the intermediate  $\beta$ -hydroxysilane is stable the olefin may be generated by further reaction with strong base, for example sodium or potassium

5 hydride. The protecting groups may then be removed as above.  $\text{TMS-CH(R}^2\text{)-X}^1\text{-X}^2\text{-R}^3$ , where  $\text{X}^1$  is S or  $\text{S(O)}_n$ , may be made from trimethylsilylmethylsulfide, for example by reaction with the appropriate electrophile in the presence of an amine base, such as triethylamine or pyridine. The thiol may be oxidized by *m*-CPBA to the sulfone.  $\text{TMS-CH(R}^2\text{)-X}^1\text{-X}^2\text{-R}^3$ , where  $\text{X}^1$  is  $\text{S(O)}_n$  and  $\text{X}^2$  is  $\text{NR}^6$ , may be prepared from trimethylsilylmethanesulfonyl chloride and  
10 the appropriate amine,  $\text{HN(R}^6\text{)-(CR}^6\text{R}^7)_i(\text{C}_6\text{-C}_{10} \text{ aryl})$ .

The compound of formula 1 where  $\text{R}^1$  and  $\text{R}^2$  are defined above,  $\text{X}^1$  is C and where  $\text{X}^2$  is N and  $\text{X}^2$  and  $\text{R}^3$  are taken together as described above may be prepared by the reaction of  $\text{HNR}^6\text{R}^3$  with protected hygromycin allyl mesylate in the presence of an amine base, such as triethylamine or pyridine. Protected hygromycin allyl mesylate may be prepared by the  
15 reaction of protected hygromycin allyl alcohol, described above, with methanesulfonyl chloride in the presence of an amine base, such as triethylamine or pyridine.

The compounds of the present invention have asymmetric carbon atoms. Compounds having a mixture of isomers at one or more centers will exist as diastereomeric mixtures, which can be separated into their individual diastereomers on the basis of their physical chemical  
20 differences by methods known to those skilled in the art, for example, by chromatography or fractional crystallization. All such isomers, including diastereomer mixtures, are considered as part of the invention.

The compounds of the present invention that are basic in nature are capable of forming a wide variety of different salts with various inorganic and organic acids. Although such salts  
25 must be pharmaceutically acceptable for administration to animals, it is often desirable in practice to initially isolate the compound of the present invention from the reaction mixture as a pharmaceutically unacceptable salt and then simply convert the latter back to the free base compound by treatment with an alkaline reagent and subsequently convert the latter free base to a pharmaceutically acceptable acid addition salt. The acid addition salts of the basic compounds  
30 of this invention are readily prepared by treating the basic compound with a substantially equivalent amount of the chosen mineral or organic acid in an aqueous solvent medium or in a suitable organic solvent, such as methanol or ethanol. Upon careful evaporation of the solvent, the desired solid salt is readily obtained. The desired acid salt can also be precipitated from a solution of the free base in an organic solvent by adding to the solution an appropriate mineral or  
35 organic acid.

Those compounds of the present invention that are acidic in nature, are capable of forming base salts with various pharmacologically acceptable cations. Examples of such salts include the alkali metal or alkaline-earth metal salts and particularly, the sodium and potassium salts. These salts are all prepared by conventional techniques. The chemical bases which are  
40 used as reagents to prepare the pharmaceutically acceptable base salts of this invention are those which form non-toxic base salts with the acidic compounds of the present invention. Such non-toxic base salts include those derived from such pharmacologically acceptable cations as

5 sodium; potassium, calcium and magnesium, etc. These salts can easily be prepared by  
treating the corresponding acidic compounds with an aqueous solution containing the desired  
alkali metal alkoxide or metal hydroxide, and then evaporating the resulting solution to dryness,  
preferably under reduced pressure. Alternatively, they may also be prepared by mixing lower  
10 alkanolic solutions of the acidic compounds and the desired alkali metal alkoxide or metal  
hydroxide together, and then evaporating the resulting solution to dryness in the same manner  
as before. In either case, stoichiometric quantities of reagents are preferably employed in order  
to ensure completeness of reaction and maximum yields of the desired final product.

The antibacterial activity of the compounds of the present invention against bacterial  
15 pathogens is demonstrated by the compound's ability to inhibit growth of defined strains of  
pathogens.

#### Assay

The assay, described below, employs conventional methodology and interpretation  
criteria and is designed to provide direction for chemical modifications that may lead to  
compounds with antibacterial activity against susceptible and drug-resistant organisms  
20 including, but not limited to, beta-lactam, macrolide and vancomycin resistance. In the assay,  
a panel of bacterial strains is assembled to include a variety of target pathogenic species,  
including representatives of antibiotic resistant bacteria. Use of this panel enables the  
chemical structure/activity relationship to be determined with respect to potency and spectrum  
of activity. The assay is performed in microtiter trays and interpreted according to  
25 Performance Standards for Antimicrobial Disk Susceptibility Tests - Sixth Edition; Approved  
Standard, published by The National Committee for Clinical Laboratory Standards (NCCLS)  
guidelines; the minimum inhibitory concentration (MIC) is used to compare strains.  
Compounds are initially dissolved in dimethylsulfoxide (DMSO) as stock solutions.

The activity of the compounds of the present invention also may be assessed in  
30 accord with Steers replicator technique which is a standard in vitro bacterial testing method  
described by Steers et al., *Antibiotics and Chemotherapy* 1959, 9, 307.

The in vivo activity of the compounds of the present invention can be determined by  
conventional animal protection studies well known to those skilled in the art, usually carried out in  
rodents.

35 According to one *in vivo* model, compounds are evaluated for efficacy in mouse  
models of acute bacterial infection. An example of one such *in vivo* system is provided as  
follows. Mice (CF1 mixed sex mice; 18-20 g) are allotted to cages upon their arrival, and  
allowed to acclimate 1-2 days before being placed in a study. The acute infection is produced  
by intraperitoneal inoculation of bacteria (*Staphylococcus aureus* strain 01A1095) suspended  
40 in 5% sterile hog gastric mucin. The inoculum is prepared by: growing the culture overnight at  
37°C on blood agar, harvesting the resulting surface growth with sterile brain heart infusion

- 5    broth, and adjusting this suspension to a turbidity that when diluted 1:10 into 5% sterile hog gastric mucin would produce 100% lethality.

     Mice (10 per group) are treated subcutaneously, at 0.5 hour and 4 hours after challenge. Appropriate non-treated (infected but not treated) and positive (vancomycin or minocycline, etc.) controls are included in each study. Percent survival is recorded after a 4-  
10   day observation period; the  $PD_{50}$  (mg/kg/dose calculated to protect 50% of infected animals) is determined by the probit method.

     The compounds of the present invention, and the pharmaceutically acceptable salts thereof (hereinafter "the active compounds"), may be administered through oral, parenteral, topical, or rectal routes in the treatment of bacterial and protozoal infections. In general, these  
15   compounds are most desirably administered in dosages ranging from about 0.2 mg per kg body weight per day (mg/kg/day) to about 200 mg/kg/day in single or divided doses (i.e., from 1 to 4 doses per day), although variations will necessarily occur depending upon the species, weight and condition of the subject being treated and the particular route of administration chosen. However, a dosage level that is in the range of about 3 mg/kg/day to about 60 mg/kg/day is most  
20   desirably employed. Variations may nevertheless occur depending upon the species of mammal, fish or bird being treated and its individual response to said medicament, as well as on the type of pharmaceutical formulation chosen and the time period and interval at which such administration is carried out. In some instances, dosage levels below the lower limit of the aforesaid range may be more than adequate, while in other cases still larger doses may be  
25   employed without causing any harmful side effects, provided that such larger doses are first divided into several small doses for administration throughout the day.

     The active compounds may be administered alone or in combination with pharmaceutically acceptable carriers or diluents by the routes previously indicated, and such administration may be carried out in single or multiple doses. More particularly, the active  
30   compounds may be administered in a wide variety of different dosage forms, i.e., they may be combined with various pharmaceutically acceptable inert carriers in the form of tablets, capsules, lozenges, troches, hard candies, powders, sprays, creams, salves, suppositories, jellies, gels, pastes, lotions, ointments, aqueous suspensions, injectable solutions, elixirs, syrups, and the like. Such carriers include solid diluents or fillers, sterile aqueous media and various non-toxic  
35   organic solvents, etc. Moreover, oral pharmaceutical compositions can be suitably sweetened and/or flavored. In general, the active compounds are present in such dosage forms at concentration levels ranging from about 5.0% to about 70% by weight.

     For oral administration, tablets containing various excipients such as microcrystalline cellulose, sodium citrate, calcium carbonate, dicalcium phosphate and glycine may be employed  
40   along with various disintegrants such as starch (and preferably corn, potato or tapioca starch), alginic acid and certain complex silicates, together with granulation binders like polyvinylpyrrolidone, sucrose, gelatin and acacia. Additionally, lubricating agents such as

5 magnesium stearate, sodium lauryl sulfate and talc are often very useful for tableting purposes. Solid compositions of a similar type may also be employed as fillers in gelatin capsules; preferred materials in this connection also include lactose or milk sugar as well as high molecular weight polyethylene glycols. When aqueous suspensions and/or elixirs are desired for oral administration, the active compound may be combined with various sweetening or flavoring agents, coloring matter or dyes, and, if so desired, emulsifying and/or suspending agents as well, together with  
10 such diluents as water, ethanol, propylene glycol, glycerin and various like combinations thereof.

For parenteral administration, solutions of an active compound in either sesame or peanut oil or in aqueous ethanol or propylene glycol may be employed. Use of a cyclodextrin derivative such as  $\beta$ -cyclodextrin sulfobutyl ether, sodium salt (see United States patent  
15 5,134,127) may also be advantageous. The aqueous solutions should be suitably buffered if necessary and the liquid diluent first rendered isotonic. These aqueous solutions are suitable for intravenous injection purposes. The oily solutions are suitable for intraarticular, intramuscular and subcutaneous injection purposes. The preparation of all these solutions under sterile conditions is readily accomplished by standard pharmaceutical techniques known to those skilled  
20 in the art.

Additionally, it is also possible to administer the active compounds of the present invention topically and this may be done by way of creams, jellies, gels, pastes, patches, ointments and the like, in accordance with standard pharmaceutical practice.

For administration to animals other than humans, such as cattle or domestic animals,  
25 the active compounds may be administered in the feed of the animals or orally as a drench composition.

The active compounds may also be administered in the form of liposome delivery systems, such as small unilamellar vesicles, large unilamellar vesicles and multilamellar vesicles. Liposomes can be formed from a variety of phospholipids, such as cholesterol,  
30 stearylamine or phosphatidylcholines.

The active compounds may also be coupled with soluble polymers as targetable drug carriers. Such polymers can include polyvinylpyrrolidone, pyran copolymer, polyhydroxypropylmethacrylamide phenyl, polyhydroxyethylaspartamide-phenol, or polyethyleneoxide-polylysine substituted with palmitoyl residues. Furthermore, the active  
35 compounds may be coupled to a class of biodegradable polymers useful in achieving controlled release of a drug, for example, polylactic acid, polyglycolic acid, copolymers of polylactic and polyglycolic acid, polyepsilon caprolactone, polyhydroxy butyric acid, polyorthoesters, polyacetals, polydihydropyrans, polycyanoacrylates and cross-linked or amphipathic block copolymers of hydrogels.

- 5       The present invention is further described and exemplified in the preparations and examples described below. In the preparations and examples, "rt" means room or ambient temperature which is a temperature within the range of about 20-25°C.

Preparation 1

- 10       Five (5) mL of a frozen lot (stored at -80°C in 20% glycerol/80% inoculum medium) of the culture *Streptomyces hygroscopicus* NRRL 2388 was used to inoculate 1L of hygromycin inoculum medium (Corn Products Corp. cerelese 13 g/L, Hubinger starch 7 g/L, Roquette corn steep solids 3 g/L, Sheffield Brand Products NZ Amine YTT 7 g/L, Baker CoCl<sub>2</sub>·6H<sub>2</sub>O 0.002 g/L, KH<sub>2</sub>PO<sub>4</sub> 0.7 g/L, MgSO<sub>4</sub>·7H<sub>2</sub>O 1.3 g/L, ammonium sulfate 0.7 g/L, Dow Chemical P2000 defoamer 1 drop/flask, Colfax soybean oil 2 drops/flask, pH to 7.0 before autoclave) in a 2.8L
- 15   Fernbach flask. The culture was grown for 3 days at 29°C with 200 rpm agitation on a 2-inch-throw shaker. This grown culture was used to inoculate 8L of sterile hygromycin fermentation medium (Albaglos calcium carbonate 1 g/L, Sheffield Brand Products NZ Amine YTT 5 g/L, Hubinger's starch 20 g/L, Archer Daniels Midland Nutrisoy flour 10 g/L, Dow Chemical P2000 defoamer 1 ml/L, Baker CoCl<sub>2</sub>·6H<sub>2</sub>O 0.002 g/L, Colfax soybean oil 2 ml/L, cerelese 10 g/L,
- 20   NaCl 5 g/L, pH to 7.0 before autoclave) in a 14 liter fermentor jar (New Brunswick Microferm, New Brunswick, New Jersey) equipped with two 4.75-inch Rushton impellers, spaced 3.75 inches from each other. The broth was incubated at 29°C with an aeration rate of 8 L/minute, and with stirring at 800 rpm. To minimize formation of *epi*-hygromycin, the pH was maintained between 6.5 and 6.9 for 126 hours, then to 6.2 to 6.6 with H<sub>2</sub>SO<sub>4</sub> (15%) for the rest of the run.
- 25   The fermentation was harvested after 143 hours total incubation. At this time, the ratio was 31:1 hygromycin A to *epi*-hygromycin.

- Six liters of broth from the above fermentation was centrifuged at 8000 rpm for approximately 15 minutes. After centrifugation, the pellet was discarded and the supernatant (at pH 6.4, assayed by HPLC to contain approximately 4.12 gms of hygromycin A activity) was
- 30   loaded on a column packed with 500 gms of an XAD-16 resin (Rohm and Haas (Philadelphia, Pennsylvania). The resin had previously been equilibrated with two bed volumes of 25 mM disodium phosphate, pH 6.0 ("buffer"). After loading, the column was washed with 2 bed volumes of buffer and 2 bed volumes of 80/20 buffer/methanol and the activity eluted with 5 bed volumes of 50/50 buffer/methanol. The cuts were assayed by HPLC and the cuts
- 35   containing the bulk of the activity (2.730 gms of hygromycin A) were combined.

- A part of this XAD-16 eluate (approximately 800 mg of hygromycin A) was diluted to 10% methanol by the addition of 1.8 liters of buffer and loaded on a 100 ml CG-161 column (TosoHaas (Montgomeryville, Pennsylvania)) which had been equilibrated with 4 bed volumes of 90/10 buffer/methanol. The product was eluted with 6 bed volumes of 50/50
- 40   buffer/methanol. The cuts were assayed by HPLC and the active cuts were combined. The

- 5 combined cut was evaporated to dryness and the solids assayed to be approximately 65% pure by weight. A small part of these solids were transferred for assay.

About 500 mg of the solids were mixed with 500 ml of water and 500 ml of ethyl acetate and stirred for 20 minutes. The two layers were separated and part of the aqueous layer was dried to obtain solids which were assayed to be approximately 52% purity by weight.

- 10 Both these solids (#34945-280-1 and 281-1) were assayed by NMR and TLC and found to contain hygromycin A activity. In addition, the NMR showed a hygromycin A/epi-hygromycin ratio of approximately 15:1.

#### Preparation 2

- Five (5) mL of a frozen lot (stored at -80°C in 20% glycerol/80% inoculum medium) of the culture *Streptomyces hygroscopicus* NRRL 2388 was used to inoculate 1L of Hygromycin inoculum medium (CPC International Inc. cerelose 13 g/L, Hubinger's starch 7 g/L, Roquette corn steep solids 3 g/L, NZ Amine YTT 7 g/L, Baker CoCl<sub>2</sub>.6H<sub>2</sub>O 0.002 g/L, KH<sub>2</sub>PO<sub>4</sub> 0.7 g/L, MgSO<sub>4</sub>.7H<sub>2</sub>O 1.3 g/L, ammonium sulfate 0.7 g/L, Dow Chemical P2000 defoamer 1 drop/flask, Colfax soybean oil 2 drops/flask, pH to 7.0 before autoclave) in a 2.8 L Fernbach flask. The culture was grown for 2 to 3 days at 29°C with 200 rpm agitation on a 2-inch-throw shaker. Two five-hundred gallon, stainless steel fermentors were loaded with 380-400 gallons of the hygromycin fermentation medium (Mineral Technologies Calcium Carbonate 1 g/L, Sheffield Brand Products NZ Amine YTT 5 g/L, Hubinger's starch 20 g/L, Archer Daniels Midland Co., Soyflour 10 g/L, Dow Chemical P2000 defoamer 1 ml/L, Baker CoCl<sub>2</sub>.6H<sub>2</sub>O 0.002 g/L, Colfax, Inc. soybean oil 2 gm/L, CPC International Inc. Cerelose 10 g/L, Cargill Inc. NaCl 5 g/L.). The medium was sterilized with 20 psig of steam for 60 minutes in the fermentors. After the medium was cooled using cooling coils in the fermentors, the pH was adjusted to 6.5-6.7. The fermentor conditions were set so that the airflow rate was 20 standard cubic feet per minute, the temperature was 28°C, the vent pressure was 5 psig, and the pH was maintained between 6.5 - 6.7 with 25% sodium hydroxide and 98% sulfuric acid. The agitation rates in the two fermentors were varied so as to maintain a dissolved oxygen level of greater than 20% of saturation level as measured in the broth immediately prior to inoculation. Upon setting the fermentor control conditions, five Fernbach inoculum flasks were combined in a sterile manner, into an 8 L aspirator bottle. This inoculum was then used for inoculation of a single, nominal, five-hundred gallon fermentor as described above. This procedure was repeated using 4 liters of inoculum so that one fermentor received four liters of inoculum and one fermenter received five liters of inoculum. Each fermentor ran for approximately 114 hours, at which time the fermentations were stopped. The broth pH was adjusted to 6.3 using 98% sulfuric acid and transferred from the fermentors for recovery.
- 40 The two fermentors referred to above (pH= 6.3, having a ratio of hygromycin A to epi-hygromycin of approximately 51:1) were filtered on a ceramic filtration system. The filtrate

- 5 (1450 gmsA, 506 gal) was loaded on a 70-gallon XAD-16 resin column. This column had been equilibrated previously with 4 bed volumes of a solution of trisodium phosphate buffer at pH 6.0 ("buffer"). After loading, the column was washed with 2 bed volumes of buffer and 2 bed volumes of 80/20 buffer/methanol. The activity was subsequently eluted from the column with 10 cuts (approximately 50 gallons each) of a solution of 50/50 buffer/methanol. The active cuts (approximately 1240 gmsA) were combined and diluted to a final concentration of 10% methanol by the addition of 1200 gallons of buffer. The use of dilution (rather than rotary evaporation) to reduce methanol concentration allowed the use of lower temperatures so as to minimize *epi*-hygromycin amounts, which tend to increase at higher temperatures. Half of this solution was loaded on a 40 liter CG-161 column (previously equilibrated with 4 bed volumes of a solution of 90/10 buffer/ methanol). After loading, the column was washed with 4 bed volumes of 80/20 buffer/methanol and eluted with 5.5 bed volumes of 50/50 buffer/ methanol. After regeneration and re-equilibration of the column, the second half of the activity was loaded on the column and eluted as described above. The combined cuts from both the runs (120 liters, approximately 1051 gmsA) were diluted to 10% methanol by the addition of buffer. This was re-loaded on the regenerated and re-equilibrated CG-161 resin column. Once the activity was adsorbed on the column, it was eluted with 4 bed volumes of methanol. This step served to both reduce the salts as well as increase the concentration of the sample prior to the final evaporation. The combined cuts from the final CG-161 column were evaporated to dryness to obtain a total of approximately 1 kgA of hygromycin A activity. The ratio of hygromycin A to *epi*-hygromycin in the final solids was about 14.5:1.
